

Unit 5

Phonology

What is Phonology?

It is a field of linguistics which studies the distribution of sounds in a language as well as the interaction between those different sounds.

What is Phonology?

Phonology tackles the following questions:

- What are the predictable sounds in a language?
- What is the phonetic context?
- Which sounds affect the meaning of words?

Phonetics Vs Phonology

- **Phonetics:** studies how speech sounds are produced, their physical properties & how they are interpreted.
- **Phonology:** studies the organization of speech sounds in a particular language.

□ Rules studied by phonologists:

- 1) Phonetics - sounds *vary with their contexts*;
- 2) Phonology - hypothesizes rules to characterize this variation.
- 3) The *sequencing and distribution* of speech sounds
- 4) Phonology is *interfaced* with other components of the grammar
(i.e. *morphology and syntax*).

Goals of a phonemic analysis

- Produce a minimal set of phonemes for the language. It will be a set smaller than the set of phones.
- With the set of phonemes, every utterance can be analyzed phonetically.

Phonology and Phonetics

Distinctive and Non-distinctive Sounds

- Distinctive (contrastive) Sounds: make a difference in meaning; e.g. /p/ & /b/ in pin, bin.
- Non-distinctive (non-contrastive) Sounds:

Do NOT make a difference in meaning; e.g. [p] in pin & spin.

Example:

/t/ in : top [t^hop]

stop [st^hop]

little [li^rl]

kitten [ki^ʔn] (n is syllabic here)

hunter [hʌⁿr]

Phoneme and Allophone

- A **phoneme**: a class of speech sounds that are identified by a native speaker as the same sound; e.g. /t/; unpredictable (given “in” in pin like the example above we CANNOT predict which sound can come before it like tin, din, kin, gin, fin, thin, sin, shin, chin)
- A phoneme is an abstract representation & cannot be pronounced (it is not a speech sound)
- A **phone**: the actual phonetic segment produced by a speaker & has been classified as belonging to some phoneme; e.g. [t^h]; predictable
- An **allophone**: a variant of a phoneme, e.g. /t/ = [ʔ], [r]

□ Rules studied by phonologists:

- 1) Phonetics - sounds *vary with their contexts*;
- 2) Phonology - hypothesizes rules to characterize this variation.
- 3) The *sequencing and distribution* of speech sounds
- 4) Phonology is *interfaced* with other components of the grammar
(i.e. *morphology and syntax*).

Distinctiveness and Contrast

- The real purpose of a speech sound is to sound *different* from the other sounds of the language.
- This is what makes a spoken vocabulary possible.
- To begin the analysis of a language's phonology, we locate all of its basic sounds.
- These basic speech sounds are the *phonemes* of the language.
- Languages vary in their *number* of phonemes.

Distinctiveness and Contrast

- E.g. **Low 11** \longrightarrow **Rotokas** (East Papuan, New Guinea)
 High 160 \longrightarrow **!Xóõ** (Khoisan, Botswana/Namibia)
 37 - 41 \longrightarrow **English** (depending on the dialect)

- If any two words of a language are pronounced differently, they must *differ in at least one phoneme*.

E.g. *time* [**t**aɪm] vs. *dime* [**d**aɪm] \longrightarrow (**minimal pairs**)

- 
- A *minimal pair* is the most effective way to show that two sounds are *distinct phonemes*.

Distinctiveness and Contrast

□ Ways to say two sounds are separate phonemes:

1) Sounds /**t**/ and /**d**/ are in *contrast*, or

2) They are *phonemically distinct*, or

3) The difference between them is *distinctive*.

■ A set like *time* [**t**aim] – *dime* [**d**aim] – *lime* [**l**aim] is a **minimal triplet**.

■ /**t**/, /**d**/, and /**l**/ are *distinct phonemes*.

Sounds that Do Not Contrast

- In any language, there are many pairs of sounds that *do not contrast*.

E.g. length of vowels in English:

save [seɪv]	safe [sɛɪf]
	
made [meɪd]	mate [mɛɪt]
	

- Although [eɪ] and [ɛɪ] are audibly different, they are not separate phonemes.
- They are in complementary distribution.

Sounds that Do Not Contrast

- Two sounds are said to be in *complementary distribution* if one sound never occurs in the environments in which the other occurs.
- [eɪ] occurs when next sound in the word is *voiced*.
- [ěɪ] occurs when next sound in the word is *voiceless*.

Phonemes as Categories

- Speakers intuitively accept [eɪ] and [ěɪ] as being the “*same vowel*.”
- Phonologists hypothesize that sounds [eɪ] and [ěɪ] form an abstract phonological *category*, i.e. the *phoneme* /eɪ/.
- The concrete, observable sounds [eɪ] and [ěɪ] are called the *allophones* of /eɪ/.

Phonemes as Categories

Abstract level:

/eɪ/

phoneme

Concrete level:

[eɪ]

[ěɪ]

allophones

used before

used before

environments for

voiced consonants

voiceless consonants

allophones

- *Phonemes* can be used to *distinguish* words from each other, but *allophones cannot*.

■ E.g. English

alveolar [n]

know	['noʊ]
annoy	[ə 'noɪ]
onion	['ʌjən]

dental [n̪]

tenth	['ten̪θ]
month	['mʌn̪θ]
panther	['pæn̪θə]

More Instances of Allophonic Variation

Abstract level:

/n/

phoneme

Concrete level: [n̥]

[n]

allophones

used before [θ]

used elsewhere

environments for
allophones

More Instances of Allophonic Variation

■ E.g. English /l/

alveolar [ɫ]	dental [l̪]	Words with [ɫ]	Words with [l]
file ['faɪɫ]	slight ['slaɪ̪t]	wealth ['weɪɫθ]	listen ['lɪsən]
fool ['fuɫ]	flight ['flaɪ̪t]	health ['heɪɫθ]	lose ['luːz]
all ['ɔɫ]	plow ['pləʊ]	filthy ['fɪɫθi]	allow ['əlaʊ]

Phonemic Transcription

- **Phonemic transcription:** sequences of phonemes of the words recorded by the linguist.
- **Phonetic transcription** includes allophonic details.
- **Orthographic transcription:** words are written down using the customary spelling system (orthography) of the language.

This is an orthographic transcription.

/ðɪs ɪz ə fəʊ'nɪmɪk træ'n'skɹɪpʃən/ (This is a *phonemic* transcription)

['d̪ðɪs ɪz ə fə'nɛɾɪʔk t̪sʰɪɛ̃ə̃n'skɹɪpʃɪn] (This is a *phonetic* transcription)

Phonological Rules

- Generalizations about the patterning of allophones can be stated as phonological rules.

e.g. /**eɪ**/ **Shortening**

*The phoneme /**eɪ**/ is realized as extra short when a voiceless consonant follows.*

- Rules are *language-specific*.
- Rules are *productive*. they extend to novel cases.

Phonological Rules

- Rules give rise to *well-formedness intuitions*.
- Phonological rules are *untaught*. they are learned intuitively by children from the ambient language data.
- Phonological rules are evidently a form of *unconscious knowledge*.

□ Expressing environments

- “/”  means “in the environment.”
- “___”  where the allophone occurs relative to its neighbors.

E.g. / ___ θ  “in the environment ‘before theta’” or “before theta.”

/ θ ___  “after theta.”

- []  Used to describe *classes* containing particular *phonetic properties*.

These are called *features*, i.e. they designate the relevant class of sounds.

Formalizing Phonological Rules

- “+” and “−” \longrightarrow before feature names to mean that a segment either *has*, or *does not have*, the *phonetic property* that a feature designates.

E.g. $\left[\begin{array}{l} +\text{consonant} \\ -\text{voice} \end{array} \right]$

/ ____] word ____

“at the end of a word”

/ [word ____

“At the beginning of a word”

Formalizing Phonological Rules

□ A **derivation** consists of a series of lines:

- The *first* line contains the *underlying representations* of a set of forms.
- The *last* line contains the *actual phonetic* forms; (often called *surface representations*).
- The *intermediate* lines show the *application of the rules* in order.
- “—” is used to designate that a rule is *inapplicable*.

Formalizing Phonological Rules

E.g.	file	slight	wealth	listen	
	/ˈfaɪl/	ˈslaɪt/	/ˈweɪθ/	/ˈlɪsən/	underlying forms
—		s ɫaɪt	—	—	/l/ Devoicing
—		—	wɛ ɮθ	—	/l/ Dentalization
	faɪɮ	—	—	—	/l/ Velarization
	[ˈfaɪɮ]	[ˈs ɫaɪt]	[ˈweɪɮθ]	[ˈɫɪsən]	surface forms

- We need not specify in this approach that [ɫ] is the elsewhere allophone.

Phonemes in Other Languages

- **Maximally ordinary** phonemic system (Maddieson 1984):

p	t	tʃ	k	i	u
b	d	dʒ	g	e	o
f	s	ʃ			a
m	n		ŋ		
		l			
		r			
w		j			

- This set constitutes all the sounds that occurred in at least **40** percent of the languages in Maddieson's (1984) survey of phonemic systems.

Phonemes in Other Languages

- Normally, an inventory will contain additional, more *unusual sounds*.
- *Unusual sounds* often occur in multiple languages in the *same geographic area*.
- A *phonemic* distinction in one language might be *allophonic* in another, e.g. *English* and *Spanish*.

Phonemes in Other Languages

❑ **English:** North American English [ɾ] is an *allophone* of the /t/ *phoneme*.

- The environment for [ɾ] is between *two vowels* of which the second is *stressless*.

	Phonemic	Phonetic		Phonemic	Phonetic	
data	/ˈdeɪtə/	[ˈdeɪɾə]	tan	/ˈtæn/	[ˈtæn]	(fails to follow a syllabic sound)
latter	/ˈlætə/	[ˈlæɾə]	cat	/ˈkæt/	[ˈkæt]	(fails to precede a syllabic sound)
eating	/ˈiːtɪŋ/	[ˈiːɾɪŋ]	attend	/əˈtend/	[əˈtend]	(following syllabic sound is stressed)

❖ Tapping

/t/ [ɾ] / [+vowel] _____
 The phoneme /t/ is realized as [ɾ] when it is preceded by a vowel and followed by a stressless vowel.

Derivations:	data	tan	cat	attend	
	/ˈdeɪtə/	/ˈtæn/	/ˈkæt/	/əˈtend/	underlying forms
	ɾ	—	—	—	Tapping
	[ˈdeɪɾə]	[ˈtæn]	[ˈkæt]	[əˈtend]	surface forms

Assignment: where should aspiration be in the examples above?
 Can the two allophonic rules ‘aspiration’ and ‘tapping’ occur together?

Phonemes in Other Languages

□ **Spanish:** /**t**/ and /**r**/ are separate *phonemes*.

['pit a]	‘century plant’	} Minimal pairs
['pi r a]	‘funeral pyre’	

- [**t**] and [**r**] are in *contrast*, and are separate phonemes.
- In **English**: [**t**] vs. [**r**] difference is *allophonic* (non-distinctive).
- In **Spanish**: [**t**] vs. [**r**] difference is *phonemic* (distinctive).
- English and Spanish are *phonetically* similar but *phonologically* different.

- ***Phonemicization*** is the body of knowledge and techniques that can be used to work out the phonemic system of a language.

□ Minimal pairs

- The most effective method in phonemicization is to look for ***minimal pairs***.
- **Minimal pairs** are two different words that differ in exactly ***one sound*** in the same location.

- The ***absence*** of a minimal pair does not prove much.

- A language will lack minimal pairs for a pair of relatively rare phonemes *by accident*.

E.g. heed [h*id*]

hid [h*id*]

hayed [h*eid*]

head [h*ɛd*]

had [h*æd*]

hide [h*a*id]

heard [h*ə*d]

who'd [h*ud*]

hood [h*u*d]

hoed [h*o*ud]

HUD [h*ʌ*d]

hod [h*ɑ*d]

how'd [h*ɑ*ud]

hawed [h*ɔ*d]

□ Near-minimal pairs

- There are cases in which it is impossible to find minimal pairs for a phoneme.
- This occurs in languages with *long words* and *large phoneme* inventories.
- **Near-minimal pairs** are pairs which would be minimal except for some evidently irrelevant difference.

E.g. some near-minimal pairs for /**ð**/ vs. /**ʒ**/:

tether ['tɛðə] vs. pleasure ['pleɪʒə]

neither ['niðə] vs. seizure ['si:ʒə]

lather ['læðə] vs. azure ['æ:ʒə]

Phonemicization

- The phonetic environment has nothing to do with whether [ð] or [ʒ] occurs.
- To find the rules that determine the appearance of [ð] vs. [ʒ] would have to make use of a completely arbitrary collection of “environments” for these phones.
- If the rules cannot be found, then an analysis that claims that [ð] and [ʒ] are allophones *cannot* be justified.
- *Near-minimal pair* method of establishing phonemes requires *more* work than minimal pairs do

Using local environments to establish complementary distribution

- Minimal and near-minimal pairs are used to establish that two sounds belong to *separate phonemes*.
- For establishing that two sounds are in the *same phoneme*, we need to establish that they are in complementary distribution.
- It is useful to follow the method of *compiling local environments*.
- **Compiling local environments:** for each sound, we construct a list of all its appearances, each time including the preceding segment, if any, and the following segment, if any.

Using local environments to establish complementary distribution

E.g. **Maasai** (Nilotic, spoken in Kenya and Tanzania)

1 [ɸar:iyoɪ] 'reddish brown'

2 [ɸiɣai] 'elsewhere'

3 [eŋgamaniyi] 'name of age-set'

4 [eŋgila] 'garment-diminutive'

5 [eŋgo:] 'advise him'

6 [eŋgoɣi] 'sin'

7 [ɪlarak] 'murderers'

8 [ɪlke:k] 'trees'

9 [ɪmɸok] 'you detain'

10 [ɪmbayiɸak] 'you are restless'

11 [ij:o:k] 'we'

12 [kaye] 'but'

13 [keɸer] 'heaven'

14 [kiɸiroɸo] 'stunted'

15 [koɣo:] 'grandmother'

16 [olduɣa] 'shop'

17 [olkiyuei] 'thorn'

18 [olpurkel] 'dry steppes'

19 [sarkin] 'intermarriage'

[k]

/ [word ____ a (12)

/ [word ____ e (13)

/ [word ____ i (14)

/ [word ____ o (15)

/ l ____ e (8)

/ l ____ i (17)

/ r ____ e (18)

/ r ____ i (19)

/ a ____]word (7, 10)

/ e: ____]word (8)

/ o ____]word (9)

/ o: ____]word (11)

[g]

/ ŋ ____ a (3)

/ ŋ ____ i (4)

/ ŋ ____ o (5)

[ɣ]

/ a ____ e (12)

/ a ____ i (10)

/ i ____ a (2)

/ i ____ i (3)

/ i ____ o (1)

/ i ____ u (17)

/ o ____ i (6)

/ o ____ o: (15)

/ u ____ a (16)

Using local environments to establish complementary distribution

- [k], [g] and [ɣ] are in *complementary distribution*.

- The environments are:

[g] / ɳ ____

[ɣ] / V ____ V (V stands for any vowel)

[k] / elsewhere

□ phonological rules:

❖ /k/ Spirantization

k → ɣ / [+vowel] ____ [+vowel]

/k/ is realized as [ɣ] between vowels.

Postnasal Voicing

k → g / ɳ ____

/k/ is realized as [g] after [ɳ].

□ phonological derivations:

‘grandmother’

/koko:/

ɣ

What is Phonology?

It is a field of linguistics which studies the distribution of sounds in a language as well as the interaction between those different sounds.

What is Phonology?

Phonology tackles the following questions:

- What are the predictable sounds in a language?
- What is the phonetic context?
- Which sounds affect the meaning of words?

Phonetics Vs Phonology

- **Phonetics:** studies how speech sounds are produced, their physical properties & how they are interpreted.
- **Phonology:** studies the organization of speech sounds in a particular language.

□ Rules studied by phonologists:

- 1) Phonetics - sounds *vary with their contexts*;
- 2) Phonology - hypothesizes rules to characterize this variation.
- 3) The *sequencing and distribution* of speech sounds
- 4) Phonology is *interfaced* with other components of the grammar
(i.e. *morphology and syntax*).

Goals of a phonemic analysis

- Produce a minimal set of phonemes for the language. It will be a set smaller than the set of phones.
- With the set of phonemes, every utterance can be analyzed phonetically.

Phonology and Phonetics

Distinctive and Non-distinctive Sounds

- Distinctive (contrastive) Sounds: make a difference in meaning; e.g. /p/ & /b/ in pin, bin.
- Non-distinctive (non-contrastive) Sounds:

Do NOT make a difference in meaning; e.g. [p] in pin & spin.

Example:

/t/ in : top [t^hop]

stop [st^hop]

little [li^rl]

kitten [ki^ʔn] (n is syllabic here)

hunter [hʌⁿr]

Phoneme and Allophone

- A **phoneme**: a class of speech sounds that are identified by a native speaker as the same sound; e.g. /t/; unpredictable (given “in” in **pin** like the example above we CANNOT predict which sound can come before it like **tin, din, kin, gin, fin, thin, sin, shin, chin**)
- A phoneme is an abstract representation & cannot be pronounced (it is not a speech sound)
- A **phone**: the actual phonetic segment produced by a speaker & has been classified as belonging to some phoneme; e.g. [**t^h**]; **predictable**
- An **allophone**: a variant of a phoneme, e.g. /t/ = [**ʔ**], [**r**]

Goals of a phonemic analysis

- Produce a minimal set of phonemes for the language. It will be a set smaller than the total number of sounds in that language
- With the set of phonemes, every utterance can be analyzed phonetically.

Allophonic rules

- The allophonic rules must be derived and they should show the realization of each phoneme in the phonetic context.
- We should be able to determine the phonemes behind the phones/sounds of a language

Allophonic rules

- For every pair of phones/sounds, we should be able to determine if they are the allophones of the same phoneme
- or if they are allophones of different phonemes.

Allophonic rules

- Whether two sounds occur in *free variation*
- only one of the sounds occur - *complementary distribution*:

Complementary distribution

Two sounds are in complementary distribution

- if the contexts in which they occur do not overlap.
- **the allophones of a phoneme must be in free variation, or in complementary distribution, or both.**

Contexts

- the analysis consists of organizing the *contexts* by seeing which sounds occur in which contexts.
- But the set of possible contexts are large.
- Start with the most general set of contexts and then refine it on the basis of the data.
- The immediate context (what immediately precedes and follows) is most likely to be relevant;
- The major sound categories and the boundaries: C, V, #, ||

Natural Classes

- A **natural class** of sounds is any complete set of sounds in a given language that share the same value for a feature or set of features.

E.g. /**m**/, /**n**/, and /**ŋ**/ in *Maasai* and in *English* form a natural class because they constitute the complete set of sounds that share the feature [+nasal].

/**t**/, and /**k**/ form a natural class in *Maasai* and in *English* because they constitute the [+stop, -voiced] sounds of the language.

❑ Using features to write general rules:

❖ Spirantization

$$\begin{bmatrix} +\text{stop} \\ -\text{voice} \end{bmatrix} \longrightarrow \begin{bmatrix} +\text{voice} \\ -\text{stop} \\ +\text{fricative} \end{bmatrix} / [+vowel] __ [+vowel]$$

A voiceless stop is realized as the corresponding voiced fricative when surrounded by vowels.

❖ Post nasal voicing

$$[+\text{stop}] \longrightarrow [+voice] / [+nasal] __$$

A voiceless stop is realized as the corresponding voiced stop when it follows a nasal consonant.

Conclusion

□ Phonological rules are based on phonetic features:

- 1) The *set of sounds a rule applies to* is a set of sounds that share a particular ***phonetic feature*** or set of ***features***.
- 2) Rules often change only *one or two features* of a sound, rather than making massive alterations.
e.g. the rules of ***Maasai*** alter only ***voicing*** and the ***stop/fricative*** distinction.
- 3) The *sounds appearing in the environment of a rule* are almost always a set of sounds that share a particular ***phonetic feature*** or ***features***.
e.g. the rule of ***English*** that shortens vowels applies before the complete *set of consonants* in English [**-voice**].

More on Phonemes

Bruce Hayes 2009

The Psychological Reality of the Phoneme

A. Audibility of fine distinctions

- *Contrastiveness* plays a major role in the perceptions of language users.
- When phonetically two sounds are heard by two different listeners **A** and **B**,
- For listener **A**, the two sounds are *contrastive* (distinguish words in her language).
- The two sounds also occur in listener **B**'s language, are *not* contrastive (*allophones*).
- **A** can hear the difference between the two sounds with perfect ease, but **B** has great difficulty.

E.g. **A** is a speaker of a dialect of *Bengali*
(dental stops *contrast* with alveolar stops)

[**t̪**an] '(vocal) tune'

[**s**a**t̪**] 'seven'

[**d̪**an] 'donation'

[**d̪**in] 'day'

[**t̪**an] 'pull!'

[**s**a**t̪**] 'sixty'

[**d̪**an] 'right (hand)'

[**d̪**im] 'egg'

B is a speaker of a variety of *American English*

(dentals occur as allophones of the alveolars, i.e. alveolars are replaced by dentals before dental fricatives)

/eɪ**t̪**θ/ [eɪ**t̪**θ] eighth

/wʊ**d̪** θɪŋk/ [wʊ**d̪** θɪŋk] would think

/tɛ**n**θ/ [tɛ**n**θ] tenth

/eɪ**t̪** ðə/ [eɪ**t̪** ðə] ate the

/sɛ**d̪** ðɪs/ [sɛ**d̪** ðɪs] said this

/ɪ**n** ðə/ [ɪ**n** ðə] in the

The Psychological Reality of the Phoneme

- Speaker **A** was **unable** to learn to hear the **Bengali** dental/alveolar distinction.
 - Speaker's **A** inability to hear the dental/alveolar distinction is **not** due to a lack of experience with dentals.
 - This is because Speaker's **A** native language **does not** have a **phonemic contrast** between alveolars and dentals.
- ❑ **To summarize:**
- Contrastiveness of *two phonetically similar sounds* leads speakers of the language that has the contrast to focus their perceptual attention on the **contrasting sounds**, and *fail* to hear other **distinctions**.
 - Native speakers hear the differences between **phonemes**, but **not** between **allophones**.

The Psychological Reality of the Phoneme

B. The notion of “same sound”

- In **phonemic theory**: Groups of mutually *non-distinctive* sounds are grouped together into categories, i.e. the *phonemes*.
- Speakers usually believe that two *allophones* of the same phoneme are the “same sound.”

E.g. vowels in *ten* and *Ted*

In *ten*, the phoneme /ɛ/ occurs before a *nasal sound*.

❖ Vowel Nasalization

[+vowel] → [+nasal] / ____ [+nasal]

A vowel is realized as nasalized when it precedes a nasal consonant.

ten	Ted	
/tɛn/	/tɛd/	underlying forms
ɛ̃	—	Vowel Nasalization
[tɛ̃n]	[tɛd]	surface forms

- For *English* speakers, *ten* and *Ted* have “the *same vowel*.”

The Psychological Reality of the Phoneme

❑ Comparison with *French* speakers:

- In French, *nasal vowels* are **phonemically** distinct from *oral vowels*.

E.g. [mɛ] ‘but’ vs. [mẽ] ‘hand’
 [tʁɛ] ‘very’ vs. [tʁẽ] ‘train’

- For *French* speakers, it is plain that [ɛ] and [ẽ] are **different** sounds.
- The difference between a *French* speaker and an *English* speaker is the **phonemic structure** of the two languages.
- Corresponding *nasal* and *oral* vowels in *French* count as **different** sounds because they are **different phonemes**.
- They count as the **same** sound in *English* because they are **allophones** of the same phoneme.

C. Foreign accents and transfer

- Speakers internalize rules that derive the various allophones in their appropriate environments.
- E.g. The behavior of speakers attempting to pronounce the sounds of a language *new* to them.
- A *foreign accent* persists even after years of practice with a second language (L2).
- The phenomenon of *mispronunciations* in a (L2) in ways attributable to the phonology of (L1) is called *transfer*.
- **Transfer** is to consider a phonology as specifying the set of *things that are pronounceable* in a given language.
- This set consists of the *legal sequences* of *phonemes*, realized as the appropriate *allophones* for their context.

The Psychological Reality of the Phoneme

□ Anything outside this *set* will involve one of three properties:

1) It can be phonologically illegal because it *contains* an *illegal* phoneme.

E.g. any utterance containing the voiced uvular fricative [ʁ] is *illegal* in English.

2) It can be phonologically illegal because it corresponds to an *illegal sequence* of phonemes.

E.g. English phonology does not permit the *phonemes order* in [bnɪk].

3) It can be phonologically illegal because it corresponds to an *impossible distribution of allophones*.

E.g. [fɪl], with a *non-velarized* [ɪ], is *illegal* in English.

- If a word of a foreign language is *phonologically illegal* in English, for any of the three reasons, it will not be pronounced correctly by English speakers.

The Psychological Reality of the Phoneme

- E.g. French *tante* ‘aunt’ [tãt] has a nasalized vowel alien to the English phoneme inventory.
- In an English accent, this comes out [tãñt], where [ñ] is a particularly short [n].
- The **derivation**:

/tant/ underlying form: choice of native phonemes

ã Nasalization: [+vowel] → [+nasal] / ____ [+nasal]

ñ Nasal Consonant $\left[\begin{array}{c} +\text{consonant} \\ +\text{nasal} \end{array} \right] \rightarrow [+short] / _ \left[\begin{array}{c} +\text{consonant} \\ -\text{voice} \end{array} \right]$

[tãñt] Shortening:
surface form

The Criterion of Phonetic Similarity

- In some cases, collecting and arranging the *non-contrasting* phonetic segments is insufficient.

E.g. [h] and [ŋ] in English.

- [h] occurs at the *beginnings* of words and before *stressed vowels*.

hill ['hɪl] ahead [ə'hɛd]

how ['haʊ] behold [bi'hɔld]

- The sound [ŋ] occurs at the ends of words, before consonants, and between vowels of which the second is stressless:

sing ['sɪŋ] sink ['sɪŋk] Singapore ['sɪŋə,pɔɪ]

pang ['pæŋ] anger ['æŋgə] dinghy ['dɪŋi]

- There are no cases of [h] occurring at *ends* of words, or *before consonants*, or *between vowels* of which the second is *stressless*.

- Likewise, there are no cases of [ŋ] occurring at the *beginning* of a word, or *before a stressed vowel*.

Therefore, [h] and [ŋ] *do not contrast*.

The Criterion of Phonetic Similarity

- Since [h] and [ɳ] do not contrast, should we regard them as *allophones* of a single phoneme?
- Phonologists' traditional answer is *no*, simply because:
- When two sounds are *allophones* of the same phoneme, they will be felt by native speakers as the *same sound*.
- This is clearly not the case for [h] and [ɳ].
- Thus, the idea that phonemes can be established purely on *distributional grounds* is *rejected*.

A. Contour segments and the segment/sequence problem

- Sounds like diphthongs ([**ai**]), affricates ([**tʃ**]), and prenasalized stops ([**mb**]) are often called *contour segments*.
- They have two phonetic qualities in sequence, but are often treated phonologically as a *single* sound.
- Recognition of the contour segments is an analytic difficulty faced in phonemicization.

E.g. we need to decide whether [**ai**] should be treated as a *diphthong* or as a sequence of /**a**/ + /**i**/.

[**tʃ**] as an *affricate* [**tʃ**], or /**t**/ + /**ʃ**/

[**mb**, **nd**, **ŋg**] as *prenasalized stops* or *nasal + stop* sequences

- This analytical issue might be called the *segment/sequence problem*.
- This problem is easy to solve if there is an actual *contrast* between *segment* and *sequence*.

Other Problems in Phonemicization

□ Polish

- [tʃ] as an *affricate* is uncontroversial because it contrasts with the *stop* + *fricative* sequence [tʃ].

[tʃi] trzy ‘three’

[tʃi] czy ‘if, whether’

- [tʃ] and [tʃ] are phonetically different ([tʃ] is longer than [tʃ]).
- The contrast between *monosegmental* /tʃ/ and *bisegmental* /tʃ/ could not be expressed.
- Thus the affricate [tʃ] must be analyzed as a *single segmental unit* in *Polish*.

Other Problems in Phonemicization

□ Mandarin

- Mandarin has the following sounds: [ə], [i], [u], [ei], and [ou].
- [e] and [o] never occur alone, but only as part of the diphthongs [ei] and [ou].
- One possible phonemicization is:

/ə/	/ei/	/əu/	/i/	/u/	underlying forms
—	ei	—	—	—	Vowel Assimilation I: ə → e / ____ i
—	—	ou	—	—	Vowel Assimilation II: ə → o / ____ u
[ə]	[ei]	[ou]	[i]	[u]	surface forms

- In this analysis we can get by with just **three** phonemes (/ə/, /i/, /u/) to derive **five** sounds.
- Since assimilation is a very common process in phonology, the rules make sense as **assimilation** rules.
- The vowel /ə/ is assimilated to [i] or [u] and become phonetically more similar to its neighbor.

B. Borrowed sounds

- When a *borrowed* sound is used for the very first time by a single speaker, it cannot count as a phoneme of the language.
- With time, borrowed words come to be used by larger numbers of speakers.
- Eventually, they are felt by native speakers to be an *integral* part of the language.
- The difficulty for phonological analysis is that the process is *gradual*.

E.g. **Japanese**: the sound [ɸ] (voiceless bilabial fricative) was plainly an *allophone* of /h/.

- It occurred only in the environment / ____ u, and was in complementary distribution with [h].
- [h] occurred in most other environments and thus was the *elsewhere* allophone.
- Under the influence of English and other foreign languages, [ɸ] has extended its usage to be the usual way to approximate a foreign [f] sound.

Other Problems in Phonemicization

- Phonemicization for [ɸ] vs. [h]:

before /a/: [ɸaito] ‘fight’ vs. [haiku] ‘type of poetry’

before /e/: [ɸeruto] ‘felt’ vs. [hema] ‘blunder’

before /o/: [ʃiɸon] ‘chiffon’ vs. [hon] ‘book’

- Considering the words in the left column to be authentic words in the vocabularies of innovating speakers,
- we must say that the dialect spoken by these speakers has acquired a *new phoneme*.
- This simply after promoting [ɸ] from *allophone* to *phoneme* status.

Free Variation

- In phonology, free variation takes two forms:

1) the phenomenon of *phonological doublets*: one word has two different phonemic forms.

E.g. in many people's speech, the word *envelope* can be pronounced as either ['envə,loʊp] or ['anvə,loʊp].

- Phonological doublets have just *one* listing for their *syntactic* properties and *meaning*, but *more* than one *phonemic representation* (figure 1.).

Syntax: common noun
Meaning: “  ”
Phonemic forms: /'envə,loʊp/, /'anvə,loʊp/

Syntax: common noun
Meaning: “  ”
Phonemic form: /kæt/

Fig. 1. Lexical entries for “cat” and “envelope”

Free Variation

2) when a **single phonemic representation** gives rise to **more** than one **phonetic form**; this is called **free variation**.

E.g. **American English**: the vowel phoneme /æ/ has a diphthongal allophone I will transcribe as [ɛ̃].

	[æ]		[ɛ̃]
Lap	/læp/ [læp]	man	/mæn/ [mɛ̃n], [mæ̃n]
pal	/pæl/ [pæl]	Spanish	/spæniʃ/ [spɛ̃niʃ], [spæ̃niʃ]
pack	/pæk/ [pæk]	dance	/dæns/ [dɛ̃ns], [dæ̃ns]

- If an /n/ follows /æ/, then there are two outputs:
- One with [ɛ̃] and one with [æ̃]. Otherwise, the observed allophone is [æ].
- Nasalization seen on both [ɛ̃] and [æ̃] is the consequence of **Vowel Nasalization**.
- The free variation between the **monophthongal** and **diphthongal** allophones can be expressed with a rule:

/æ/ **Diphthongization** (preliminary)

æ → ɛ̃ / ____ n

The phoneme /æ/ is realized as [ɛ̃] when it precedes /n/.

Free Variation

- Together with *Vowel Nasalization*, /æ/ *Diphthongization* suffices to derive the [ẽ̃] variants:

ban: /bæ̃n/ underlying form
 bɛ̃n /æ/ Diphthongization
 bẽ̃n Vowel Nasalization
 [bẽ̃n] surface form

- The speaker may apply the rule or not; i.e. /æ/ Diphthongization *applies optionally*.

❖ /æ/ Diphthongization (revised)

æ → ɛ̃ / ____ n (optional)

The phoneme /æ/ *may be realized as* [ɛ̃] *when it precedes* /n/.

Free Variation

- The effects of optional rules can be shown with *branching derivations* which include arrows to indicate what happens when an optional rule does or does not apply.

Contextually Limited Contrasts and Phonotactics

- **Phonemic contrast** is often not an *across-the-board* matter, but is confined to particular contexts.

E.g. in **Toba Batak** (Austronesian, Sumatra)

- There is a general contrast between *voiced* and *voiceless stops* and *affricates*.

[**p**inoppar] ‘descendant’

[**b**ian] ‘dog’

[**t**uak] ‘palm wine’

[**d**ukkar] ‘let out’

[**k**orea] ‘Korea’

[**g**arut] (name of town in Indonesia)

- Many words of Toba Batak also end in *voiceless stops*:

[hotop] ‘fast’

[surat**t**] ‘letter’

[halak**k**] ‘man’

- **No** word in the language ever ends in a *voiced stop*.
- We have a phonological contrast of voicing, but it is a *contextually limited contrast*.

□ Analyzing phonotactics and contextually limited contrast

- Two formal approaches to contextually restricted contrast:

1) We write rules that would have the effect of *eliminating* the contrast.

❖ Final Devoicing (Toba Batak)

$[+stop] \rightarrow [-voice] / ______]word$

Stops are devoiced at the end of a word.

2) phonological theory involves not just rules but also *constraints*.

- A **constraint** is a formal characterization of a structure that is *illegal* in a particular language.

❖ Constraint against Final Voiced Stops (Toba Batak)

* $\begin{bmatrix} +stop \\ +voice \end{bmatrix} / ______]word$

It is illegal to have a voiced stop in word-final position.

Such constraints are sometimes called *phonotactic constraints*.

Phonotactics are a general term for the principles of phonological *well-formedness* in a particular language.

□ Contrast with zero

- The notion of phonological contrast can be broadened to include *contrast with zero*.

E.g. **English** allows contrasts like tax [tæks] vs. tack [tæk].

The [s] of tax is said to be in contrast with *zero*.

t	æ	k	s
t	æ	k	∅

- ∅ is the symbol representing the null string.
- Contrast with zero can also be *contextually limited*.
- **Toba Batak** never permits *two consonants* to occur at the *end of a word* like English.
- In **Toba Batak** consonants may contrast with *zero* only when they are *adjacent to a vowel*.
- To ban the CC vs. C contrast in final position, we formulate either a *rule* or a *constraint*:

Contextually Limited Contrasts and Phonotactics

- To ban the CC vs. C contrast in final position, we formulate either a *rule* or a *constraint*:

❖ Rule: Cluster Simplification

$C \rightarrow \emptyset / C ___]_{\text{word}}$

Delete a word-final consonant if a consonant precedes.

❖ Constraint: Ban on final clusters

$*CC]_{\text{word}}$

- Comparing the two approaches, we see one possible *objection* to the *rule-based theory*:
- It often forces us to make *arbitrary* analytic decisions.
- There seems to be no reason to delete the second consonant rather than the first.
- Both rules would suffice to enforce the *one-consonant* limit.
- Often, there is further *evidence* from the language that tells us which rule is *correct*.

Conclusion

- In analyzing a language, we seek first to *isolate* its inventory of phonemes.
- The allophonic variation of phonemes, both *contextual* and *free*, must be characterized with appropriate *phonological rules*.
- The limitations on *contrast*, both between *phonemes* and between *phonemes and zero*, must be characterized with *rules* or *constraints*.
